

APPLICATION NOTE

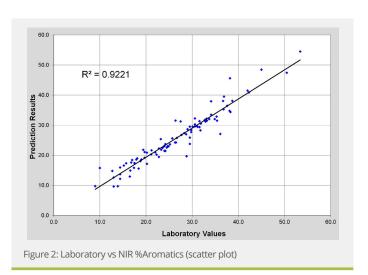

Percent Aromatics in Gasoline

The aromatic content of gasoline determines many of its combustion properties. Since it also impacts the environmental characteristics of the fuel it is desirable to have accurate measurements of this parameter. The traditional analytical method for measuring aromatics is either gas chromatography (GC) or an older method entitled fluorescent indicator adsorption (FIA), both of which are time and labor intensive. This note will discuss the use of our hardware and software tools for the measurement of % aromatics in fuel products using fiber optic-based, Near-Infrared (NIR) spectroscopy. NIR can be applied in real time directly in process monitoring or as a laboratory procedure. In either case NIR is a time and money saving alternative to traditional methods.

Measurement Background

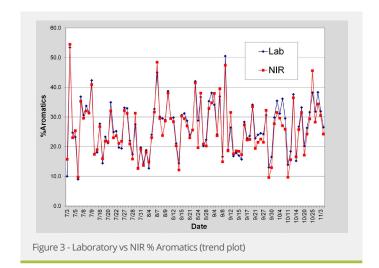

The NIR region of the electromagnetic spectrum allows the use of the overtone and combination bands of the C-H, O-H, and N-H fundamentals. By measuring the NIR spectra of a series of fuel samples of known aromatic concentration, a quantitative model can be developed which will allow the measurement of % aromatics in future samples based only on their NIR spectrum. Our analyzer systems use fiber optics to allow the sample probe to be located in remote locations away from the spectrophotometer itself.

Experimental

The NIR spectra of a group of a large number of different process gasoline samples with known aromatics concentration ranging between 2.0 to 62.0% aromatics were measured between 1000 and 1600 nm using a NIR-O™ process analyzer spectrometer. Figure 1 shows the absorbance spectra of some representative gasoline samples collected using an on-line process probe with a 1 cm pathlength. For this application, data preprocessing consisted of a simple 2-point baseline correction to remove any offset. The spectra and concentration data were submitted to a third party software and a calibration model was developed using PLS regression methodology. For a discussion of PLS and other multivariate calibration techniques please see Martens & Naes¹ and ASTM E1655².

Results

The model was used to predict aromatic concentrations over a 3 month time period using an in-situ probe inserted in a gasoline process stream measuring in real time. The results for this are shown in Figure 2 as a scatter plot and in Figure 3 as a trend plot. The model produced a prediction RMSEP (root mean square error of prediction) of 2.5% aromatics. This is in good agreement with the accuracy of the standard laboratory method.

Conclusion

The measurement of aromatics in gasoline using NIR spectroscopy is both fast and reliable utilizing our hardware and software tools described here. This method minimizes the need for laboratory sample collection. Results are available in real-time (seconds) for aromatics content and multiple other parameters in other complex hydrocarbon streams. For more detailed information regarding system specifications and capabilities please contact a Process Insights sales or technical specialist.

GAIN REAL-TIME INSIGHT INTO YOUR PROCESS

Process Insights manufactures and delivers premium sensors, monitors, detectors, analyzers, instrumentation, and software that are mission-critical to keep your operations, personnel, and the environment safe – every day across the globe.

Get the most reliable, precision analytical technologies available on the market today. We will work to match your needs and budget, and provide the optimal, and most stable process analysis solution for your application.

CENTERS OF EXCELLENCE | PROVIDING PROVEN SOLUTIONS

Process Insights is committed to solving our customers' most complex analytical, process, and measurement challenges everyday.
